

FOR GENERATIONS

**Report Title:** Peace River Site C Development – Fisheries Habitat and Tributary Surveys  
1990 Studies

**Issuer:** Tim Slaney, Aquatic Resources Ltd

**Date:** July, 1991

**NOTE TO READER:**

**INFORMATION CONTAINED IN THIS REPORT MAY BE OUT OF DATE AND BC HYDRO MAKES NO STATEMENT ABOUT ITS ACCURACY OR COMPLETENESS. USE OF THIS REPORT AND/OR ITS CONTENTS IS AT THE USER'S OWN RISK.**

**During Stage 2 of the Site C Project, studies are underway to update many of the historical studies and information known about the project.**

**The potential Site C project, as originally conceived, will be updated to reflect current information and to incorporate new ideas brought forward by communities, First Nations, regulatory agencies and stakeholders. Today's approach to Site C will consider environmental concerns, impacts to land, and opportunities for community benefits, and will update design, financial and technical work.**

## PART IV

### SUMMARY

#### 4.1 CONCLUSIONS

At the end of the second year of studies, a number of areas remained to be investigated. However, the information collected to date is sufficient to support some conclusions about habitats and fish populations in the Peace River tributaries as well as their enhancement potential.

##### 4.1.1 Habitat Inundation

The composition of the aquatic habitats which will be flooded by the Site C development is summarized in Table 36 which will be revised and completed in a subsequent draft. In general, the inundated tributary habitat is similar to that in the adjoining reaches and losses of unique habitat types are minimal. The more significant losses include:

- Shallow glide habitats in the Moberly River which are used by spawning mountain whitefish and possibly Arctic grayling.
- spawning habitats used by rainbow trout in Maurice Creek.
- Marginal spawning habitats in Lynx Creek.

Lost habitats in Wilder, Cache, Halfway and Farrell systems appear to be less significant in terms of fish production.

##### 4.1.2 Fish Populations

- a). The Plateau Tributaries, particularly Cache Creek, Wilder Creek, Farrell Creek, Cameron River and Ground Birch Creek appear to have very few sportfish and high densities of suckers and minnows. Production of sportfish in these systems seems to be limited by the high silt loads and instability in the spring followed by high water temperatures during summer and low flows during both summer and winter.
- b). Lynx Creek contains two populations of rainbow trout. In the upstream areas, which are inaccessible to Peace River fish, there is a resident population of small rainbow trout. In the lower reaches, juvenile rainbow trout appear to rear for up to three years before moving out to the Peace

**Table 36**  
Summary of habitat areas<sup>1</sup> to be inundated by a Site C reservoir.

Habitat type	Peace	Moberly <sup>4</sup>	Wilder <sup>4</sup>	Cache <sup>4</sup>	Halfway	Farrell <sup>4</sup>	Lynx <sup>4</sup>	Maurice <sup>4</sup>
Glide (<1 m) <sup>2</sup>	631				47.4			
Glide (>1 m)	20,500				518			
GRC <sup>3</sup> (<1 m)	-				-			
GRC (>1 m)	-				-			
Pool (<1 m)	902				8.38			
Pool (>1 m)	389				-			
Riffle	3,010				595			
Rapid & Cascade	-				-			
Slough	-				-			
Total	25,400				1,170			

1 - m<sup>2</sup> x 1,000 during September, 1989.

2 - Mean maximum depth.

3 - Glide riffle complex. Individual features too small to separate at survey scale.

4 - Revisions required. Will be included in final draft.

River mainstem. Habitat capacity in this area appears to be quite limited due in part, to the large amounts of silt flowing out of Brenot Creek.

- c). Maurice Creek contained the highest densities of rainbow trout of all the tributaries examined and appeared to be the most important spawning area for rainbow trout from the Peace River. During the spring, the system was also used by lake whitefish, mountain whitefish, northern pike, and Arctic grayling. No fish were found above a series of falls located 3 - 7 km from the mouth.
- d). Mature mountain whitefish were captured from the Moberly River in early October where few adults had been caught previously in early September. In addition, juvenile Arctic grayling were captured although few adults were observed. The Moberly River appears to be an important spawning area for these species. Moderate densities of Northern pike were found in Reaches 3 and 5.
- e). In early June, an initial study of the Moberly River was conducted around the mouth to determine if concentrations of spawning sportfish were accumulating in preparation to move upstream and spawn. Only mountain whitefish and small numbers of Arctic grayling, northern pike, burbot and kokanee were captured.

No accumulations of spawning sportfish were found within the river during June. Reach 1 appeared to be extremely unstable and silty and not very suitable as spawning habitat for sportfish. The only sportfish that were sampled from Reach 1 were small numbers of juvenile mountain whitefish and one bull trout. Reach 2 appeared to have more suitable habitat. In this reach large concentrations of young of the year mountain whitefish were found in low velocity habitat supporting earlier suggestions that this species probably utilizes this reach for spawning in the fall. The reach may also be used for spawning by Arctic grayling as a four year old adult and a few juveniles were captured in the few sites sampled. From this and previous studies it appears that the only Peace River sportfish that use the Moberly River as spawning habitat are mountain whitefish and perhaps Arctic grayling. Rainbow and walleye not been found below the lake although there are reports of rainbow trout in the headwaters (N.E. Down, MOE, pers. comm.).

- f). Mountain whitefish were the most prevalent species in the five Halfway River tributaries that were sampled in August. The largest systems, the

Graham River, Chowade River, and Cypress Creek, appear to be important habitat for spawning and the rearing of juveniles and adults. Although the two smallest systems, Blue Grave and Horseshoe creeks, contained high densities of juveniles in the lower reaches, the lack of young of the year suggests that these systems do not provide significant spawning habitat. Older juveniles from other systems possibly move into the lower reaches to rear in these two small creeks.

- g). Blue Grave and Horseshoe Creeks appear to provide spawning and rearing habitat for rainbow trout as moderate densities of juveniles were captured at all the sites sampled. The larger systems, particularly the Graham and Chowade systems, provide foraging habitat for the adults and possibly little spawning habitat as no juveniles were observed.
- h). Bull trout were found in all the systems except Cypress Creek. Blue Grave and Horseshoe Creek appear to provide spawning for this species as significant numbers of juveniles were captured. Adults were also sampled from the upper site on Blue Grave Creek. Adults were captured in the Graham and Chowade rivers, but the densities appeared low.
- i). Arctic grayling were captured in all of the systems, but in small numbers. No young of the year were captured in any of the systems studied during 1990 although they have previously been collected from the Moberly, Cache, Cameron, Ground Birch, Graham, Colt and Colt systems. In addition, spawning migrations have been observed in Farrell, Lynx and Maurice creeks. Despite these observations, the details of habitat usage by spawning and rearing and rearing Arctic grayling in the Site C area remain largely unknown.

#### **4.1.3 Enhancement/Mitigation Potential**

- a). Spawning and rearing habitats within the Site C reservoir are likely to be limited. The possibility of increasing fish utilization of the reservoir's inlet arms, particularly the Moberly Arm should be investigated along with opportunities to take advantage of any rock or gravel structures which are required during reservoir construction or operation.
- b). Sportfish, particularly Arctic grayling, rainbow trout, bull trout or walleye are likely to require hatchery support. Hatchery incubation would compensate for the lack of spawning habitat in immediate tributaries to the reservoir as well as permitting increased angling pressure in the upper

Halfway River tributaries. Perhaps more importantly, warmer hatchery environments would encourage growth at critical juvenile stages which are likely to be impaired by low temperatures in the reservoir.

- c). Kokanee from upstream areas currently rear in the Site C segment of the Peace River. Although these fish could be quite successful in the proposed reservoir, the population is not self perpetuating as no spawning has been observed. Development of spawning or incubation facilities could contribute an important sport or forage species to the reservoir.
- d). Productivity of the Site C reservoir is likely to be limited by low water temperatures and high flushing rates. It is unlikely that substantial changes can be made in mainstem areas. However, it may be possible to increase production through summer fertilization of the Moberly arm which will have a much lower flushing rate.
- e). Spawning success in the Moberly River appears to be limited by channel instability and poor water quality during freshet flows. Spawning habitats may be further constrained by impoundment which would inundate large areas of the shallow glide habitat currently used by mountain whitefish and possibly Arctic grayling. It may be possible to mitigate the habitat loss through side channel development.
- f). Although the Moberly River has populations of sportfish in the reaches between the Peace River and Moberly Lake, there is little access and no facilities for fishermen. Reach 3 appears to have an abundance of northern pike that is not fished. A road into the Reach 3 along with a boat launch and possibly a campsite would be one method of increasing the angling potential and use of this system. As Reach 3 is mainly slow flowing glide, it may also be an area of interest to canoeists.
- g). Because of substrate instability, lack of water storage, and high sediment load, there is little opportunity for mitigation or enhancement work on the plateau systems.
- h). Maurice Creek appears to be the most important area for spawning rainbow trout from the Peace River. However, capacity is limited by poor substrates and impassable falls. It appears that construction of a spawning/rearing channel in upper Reach 1 could expand the system's productivity. Channel development feasibility should be investigated further.

- i). Above the waterfalls of Maurice Creek there appears to be a large area of moderate quality habitat which could be stocked with rainbow trout. The trout are unlikely to residualize there but downstream emigration would contribute to stocks in the Peace River.
- j). The enhancement potential of Lynx Creek is limited due to the small base flow and heavy silt load. Some improvement could however be made by piping the Brenot Creek springs away from significant silt sources.
- k). Most habitats in the Graham, Chowade and Cypress systems do not appear to be near capacity. Additional angling opportunities could be created by stocking bull trout and rainbow trout in these systems.

## **4.2 RECOMMENDED FUTURE STUDIES**

Some of the problems worthy of further attention are listed below.

- a). Characteristics of reservoir inlet arms.  
One of the biggest restrictions to summer fish production in the Site C reservoir is likely to be low water temperature. As the tributaries are likely to be much warmer, some work should be done to examine the thermal regimes in these areas and how they can best be used. It may be that the warm water will merely form a thin lens over colder Peace River water. None the less, the distribution of warm water may have important enhancement implications.

Flow rates and characteristics of the Moberly arm should be given particular attention and the feasibility of enhancing production through fertilization should be investigated.

- b). Walleye stock characteristics  
The microhabitat preferences and thermal responses of Peace River walleye should be investigated in detail. The literature suggests that the proposed reservoir may be too cold for this species to feed or grow. However, as the river is presently cooler than the proposed reservoir yet supports a moderate walleye population, there is reason to suspect that walleye of the Peace River have adapted to cool temperatures. This characteristic should be investigated further before mitigation plans are finalized.

c). Overwintering habitats

Biophysical observations made during this survey support the RRCS (1979) hypothesis that a lack of suitable habitat severely limits fish populations overwintering in Peace River tributaries. The summer/fall surveys did reveal a few deep water refugia but we were unable to identify groundwater sources which might also provide refuge. A few obvious seepages on high banks were noted but those within the watercourses could not be detected. A winter overflight of the study area should be conducted to look for possible ground water supported refuges, or areas where seepages could be developed to provide refuges. Small seepages are likely to be covered by ice and snow. However, seepages large enough to support enhancement or mitigation projects are often visible as open water areas or major ice buildups.

Similarly, although the lack of overwintering habitat is evident, it is difficult to assess the importance the shortage. The Peace River provides large amounts of over wintering habitat and some fish have been observed to drop down from the tributaries to overwinter there (RRCS 1979, Pattendon and Ash 1990). It is however, difficult to assess the relative importance of tributary and instream overwintering without further study.

d). Lynx Creek

The groundwater sources on Brenot Creek should be investigated. At present, these seepages are a major source of the silt which limits fish production in this system. The springs are relatively small and the surrounding soils are very unstable. Wells might permit the water to be piped to the creek. This would limit silt and stabilize the banks. Alternatively, the groundwater might be diverted into pools either to provide overwintering/rearing habitat or to allow the silt to settle.

e). Moberly River

The Moberly River supports the most diverse assemblage of fish species seen in the Peace River tributaries. However, Reach 1 appears to have little potential for spring spawners due to its unstable nature. The river does not seem to be utilized as spawning habitat by rainbow trout as none of the previous studies have located rainbow trout in any of the reaches below Moberly Lake.

Arctic grayling have been found in the Moberly River in low numbers but no data have been collected on the extent to which Arctic grayling from the Peace River utilize the system for spawning and where spawning areas

exist. Reach 2 and 3 would appear to present the best spawning habitat for Arctic grayling, although Reach 2 was only examined for one day during May and June 1990 and Reach 3 was not examined at all. These two Reaches warrant more examination during the early spring to more accurately determine the Arctic grayling populations present and their habitat usage.

Fall spawners, particularly mountain whitefish were found throughout reaches 2 and 3 during 1989. The information suggests that the segment of Reach 1 which will be impacted by reservoir development is used more for migration than spawning. However, the data are less than conclusive and there may be an element of inter-annual variation. Further study is warranted

f). **Blue Grave, Horseshoe and Colt Creeks**

These smaller creeks in the upper Halfway area appear to be important spawning and rearing areas for bull trout and rainbow trout. Migration studies including counting fences, and detailed habitat utilization studies should be conducted in the spring for rainbow trout and in the fall for bull trout. The information would provide a better understanding of the contribution of these systems to the fisheries of the area. It would also facilitate development of enhancement or stocking programs.

g). **Colt Creek**

Beaver dams in lower Colt Creek should be monitored to determine if they obstruct migration from the Graham River mainstem. If the dams are not passable, or if the dams are not flushed out by spring freshets, then it may be advantageous to remove the dams occasionally.

h). **Graham and Chowade Rivers**

It appears that the Graham River and perhaps the Chowade River are important areas for Halfway River and Peace River bull trout. Snorkel surveys and tag/recovery programs during the summer and fall should be conducted in sections of these two systems to assess the population size and to help determine the migration patterns of this species. This would facilitate the development of stocking programs which would not interfere with natural production. These fish occasionally reach large sizes and are therefore a popular sportfish. Enhancement efforts in this area are likely to be well received.

Bull trout from the Peace River have been shown to migrate upstream as far as Christina Falls on the Graham River. Prior to the establishment of enhancement programs for the upper tributaries, the relationship between existing stocks and those from the Peace River mainstem should be better understood. This would be best undertaken through continued tagging and tracking studies.

#### **ACKNOWLEDGEMENTS**

Wendy Collett, Lynn Finlay, Mike Robertson, and Mike Robinson assisted with the field operations. Michelle Leptich aged the scale samples and the water samples were analyzed by PowerTech Inc. in Vancouver.

Glen Singleton served as B.C. Hydro Environmental Coordinator for the project and provided both direction and assistance. The report was reviewed by Gary Ash and Melody Farrell. Their helpful comments were much appreciated.
